

HIGHLIGHTS OF PRESCRIBING INFORMATION

These highlights do not include all the information needed to use ZILRETTA safely and effectively. See full prescribing information for ZILRETTA.

ZILRETTA® (triamcinolone acetonide extended-release injectable suspension), for intra-articular use
Initial U.S. Approval: 1957

INDICATIONS AND USAGE

ZILRETTA is an extended-release synthetic corticosteroid indicated as an intra-articular injection for the management of osteoarthritis pain of the knee. (1)

Limitation of Use

The efficacy and safety of repeat administration of ZILRETTA have not been demonstrated. (2.1)

DOSAGE AND ADMINISTRATION

- 32 mg (5 mL) administered as a single intra-articular injection in the knee. (2.1)
- See [Instructions for Use \(IFU\)](#) for instructions on reconstitution of ZILRETTA with the supplied diluent. (2.2)
- It is normal for some residue to be left behind on the vial walls after withdrawing the suspension. (2.2)
- ZILRETTA is NOT substitutable with other formulations of injectable triamcinolone acetonide. (2.3)

DOSAGE FORMS AND STRENGTHS

ZILRETTA is an injectable suspension that delivers 32 mg of triamcinolone acetonide. It is supplied as a single-dose kit containing one vial of ZILRETTA microsphere powder, one vial of 5 mL diluent, and one sterile vial adapter. (3)

FULL PRESCRIBING INFORMATION: CONTENTS*

1 INDICATIONS AND USAGE

2 DOSAGE AND ADMINISTRATION

- Important Dosage and Administration Information
- Preparation and Administration of Intra-Articular Suspension
- Non-Interchangeability with Other Formulations of Triamcinolone Acetonide for Intra-articular Use

3 DOSAGE FORMS AND STRENGTHS

4 CONTRAINDICATIONS

5 WARNINGS AND PRECAUTIONS

- Warnings and Precautions Specific for ZILRETTA
- Serious Neurologic Adverse Reactions with Epidural and Intradiscal Administration
- Hypersensitivity Reactions
- Joint Infection and Damage
- Increased Risk of Infections
- Alterations in Endocrine Function
- Cardiovascular Effects
- Renal Effects
- Increased Intraocular Pressure
- Gastrointestinal Perforation
- Alterations in Bone Density
- Behavioral and Mood Disturbances

6 ADVERSE REACTIONS

- Clinical Trials

CONTRAINDICATIONS

Patients with hypersensitivity to triamcinolone acetonide or any component of the product. (4)

WARNINGS AND PRECAUTIONS

- Intra-articular Use Only:** Do not administer ZILRETTA by epidural, intrathecal, intravenous, intraocular, intramuscular, intradermal, or subcutaneous routes. (5.1)
- Serious Neurologic Adverse Reactions with Epidural and Intradiscal Administration:** Serious neurologic events have been reported following epidural or intrathecal corticosteroid administration. Corticosteroids are not approved for this use. (5.2)
- Hypersensitivity Reactions:** Serious reactions have been reported with triamcinolone acetonide injection. Institute appropriate care upon occurrence of an anaphylactic reaction. (5.3)
- Joint Infection and Damage:** May cause joint pain accompanied by joint swelling. If this occurs, conduct appropriate evaluation to exclude septic arthritis and institute appropriate antimicrobial therapy if septic arthritis is confirmed. (5.4)

ADVERSE REACTIONS

Most commonly reported adverse reactions (incidence $\geq 1\%$) in clinical studies include sinusitis, cough, and contusions. (6)

To report SUSPECTED ADVERSE REACTIONS, contact Pacira Pharmaceuticals, Inc. at 1-844-353-9466 or FDA at 1-800-FDA-1088 or www.fda.gov/medwatch.

See 17 for PATIENT COUNSELING INFORMATION.

17 PATIENT COUNSELING INFORMATION

*Sections or subsections omitted from the full prescribing information are not listed.

FULL PRESCRIBING INFORMATION

1 INDICATIONS AND USAGE

ZILRETTA (triamcinolone acetonide extended-release injectable suspension) is indicated as an intra-articular injection for the management of osteoarthritis pain of the knee.

Limitation of Use

The efficacy and safety of repeat administration of ZILRETTA have not been demonstrated. [see *Dosage and Administration* (2.1)].

2 DOSAGE AND ADMINISTRATION

2.1 Important Dosage and Administration Information

- ZILRETTA is administered as a single intra-articular extended-release injection of triamcinolone acetonide, to deliver 32 mg (5 mL).
- ZILRETTA is for intra-articular use only. Do NOT administer by the following routes: epidural, intrathecal, intravenous, intraocular, intramuscular, intradermal, subcutaneous.
- ZILRETTA is not suitable for use in small joints, such as the hand.
- The efficacy and safety of repeat administration of ZILRETTA have not been demonstrated [see *Adverse Reactions* (6) and *Nonclinical Toxicology* (13.2)].
- The efficacy and safety of ZILRETTA for management of osteoarthritis pain of shoulder and hip have not been evaluated.

2.2 Preparation and Administration of Intra-Articular Suspension

Refer to the *Instructions for Use* for directions on the preparation and administration of ZILRETTA.

ZILRETTA is supplied as a single-dose kit containing a vial of ZILRETTA microsphere powder, a vial of sterile diluent, and a sterile vial adapter.

ZILRETTA must be prepared using the diluent supplied in the kit.

Preparation of ZILRETTA requires close attention to the Instructions for Use to ensure successful administration.

Use proper aseptic technique throughout the dose preparation and administration procedure.

ZILRETTA is a suspension product and it is normal for some residue to be left behind on the vial walls after withdrawing the contents.

Promptly inject ZILRETTA after preparation to avoid settling of the suspension. If needed, the ZILRETTA suspension can be stored in the vial for up to 4 hours at ambient conditions. Gently swirl the vial to resuspend any of the settled microspheres prior to preparing the syringe for injection.

The usual technique for intra-articular injection should be followed. Aspiration of synovial fluid may be performed based on clinical judgment prior to administration of ZILRETTA.

2.3 Non-Interchangeability with Other Formulations of Triamcinolone Acetonide for Intra-articular Use

ZILRETTA is NOT substitutable with other formulations of injectable triamcinolone acetonide.

3 DOSAGE FORMS AND STRENGTHS

ZILRETTA is an injectable suspension that delivers 32 mg of triamcinolone acetonide. ZILRETTA is supplied as a single-dose kit, containing:

- One vial of ZILRETTA white to off-white microsphere powder
- One vial of 5 mL sterile, colorless to pale yellow, clear diluent
- One sterile vial adapter

4 CONTRAINDICATIONS

ZILRETTA is contraindicated in patients who are hypersensitive to triamcinolone acetonide, corticosteroids or any components of the product [*see Warnings and Precautions (5.3) and How Supplied/Storage and Handling (16)*].

5 WARNINGS AND PRECAUTIONS

5.1 Warnings and Precautions Specific for ZILRETTA

ZILRETTA has not been evaluated and should not be administered by the following routes:

- Epidural
- Intrathecal
- Intravenous
- Intraocular
- Intramuscular
- Intradermal
- Subcutaneous

[*see Warnings and Precautions (5.2)*].

5.2 Serious Neurologic Adverse Reactions with Epidural and Intrathecal Administration

Serious neurologic events, some resulting in death, have been reported with epidural injection of corticosteroids. Specific events reported include, but are not limited to, spinal cord infarction, paraplegia, quadriplegia, cortical blindness, and stroke [*see Adverse Reactions (6)*]. These serious neurologic events have been reported with and without use of fluoroscopy.

Reports of serious medical events have been associated with the intrathecal route of corticosteroid administration [*see Adverse Reactions (6)*].

The safety and effectiveness of epidural and intrathecal administration of corticosteroids have not been established, and corticosteroids are not approved for this use. In particular, the formulation of ZILRETTA should not be considered safe to use for epidural or intrathecal administration.

5.3 Hypersensitivity Reactions

Rare instances of anaphylaxis have occurred in patients with hypersensitivity to corticosteroids. Cases of serious anaphylaxis, including death, have been reported in individuals receiving triamcinolone acetonide injection, regardless of the route of administration [*see Adverse Reactions (6)*]. Institute appropriate care upon occurrence of an anaphylactic reaction.

5.4 Joint Infection and Damage

Intra-articular injection of corticosteroid may be complicated by joint infection. A marked increase in pain accompanied by local swelling, further restriction of joint motion, fever, and malaise are suggestive of septic arthritis. If this complication occurs and a diagnosis of septic arthritis is confirmed, institute appropriate antimicrobial therapy [*see Adverse Reactions (6)*].

Avoid injection of a corticosteroid into an infected site. Local injection of a corticosteroid into a previously infected joint is not usually recommended. Examine any joint fluid present to exclude a septic process.

Corticosteroid injection into unstable joints is generally not recommended.

Intra-articular injection may result in damage to joint tissues.

5.5 Increased Risk of Infections

Intra-articularly injected corticosteroids are systemically absorbed. Patients who are on corticosteroids are more susceptible to infections than are healthy individuals. There may be decreased resistance and inability to localize infection when corticosteroids are used. Infection with any pathogen (viral, bacterial, fungal, protozoan, or helminthic) in any location of the body may be associated with the use of corticosteroids alone or in combination with other immunosuppressive agents. These infections may be mild to severe. With increasing doses of corticosteroids, the rate of occurrence of infectious complications increases. Corticosteroids may also mask some signs of current infection.

Advise patients to inform their health care provider if they develop fever or other signs or symptoms of infection. Advise patients who have not been vaccinated to avoid exposure to chicken pox or measles. Instruct patients to contact their health care provider immediately if they are exposed [*see Patient Counseling Information (17)*].

5.6 Alterations in Endocrine Function

Corticosteroids can produce reversible hypothalamic-pituitary-adrenal axis suppression, with the potential for adrenal insufficiency after withdrawal of treatment, which may persist for months.

In situations of stress during that period (as in trauma, surgery, or illness), institute corticosteroid replacement therapy.

Metabolic clearance of corticosteroids is decreased in hypothyroid patients and increased in hyperthyroid patients.

5.7 Cardiovascular Effects

Corticosteroids can cause elevations of blood pressure, salt and water retention, and increased excretion of potassium. These effects are less likely to occur with synthetic derivatives.

Monitor patients with congestive heart failure or hypertension for signs of edema, weight gain, and imbalance in serum electrolytes. Dietary salt restriction and potassium supplementation may be necessary.

5.8 Renal Effects

Corticosteroids can cause salt and water retention, and increased excretion of potassium. These effects are less likely to occur with synthetic derivatives. All corticosteroids increase calcium excretion.

Monitor patients with renal insufficiency for signs of edema, weight gain, and imbalance in serum electrolytes. Dietary salt restriction and potassium supplementation may be necessary.

5.9 Increased Intraocular Pressure

Corticosteroid use may be associated with development or exacerbation of increased intraocular pressure.

Monitor patients with elevated intraocular pressure for potential treatment adjustment.

5.10 Gastrointestinal Perforation

Corticosteroid administration is associated with increased risk of gastrointestinal perforation in patients with certain GI disorders such as active or latent peptic ulcers, diverticulosis, diverticulitis, ulcerative colitis and in patients with fresh intestinal anastomoses.

Avoid corticosteroids in these patients because signs of peritoneal irritation following gastrointestinal perforation may be minimal or absent.

5.11 Alterations in Bone Density

Corticosteroids decrease bone formation and increase bone resorption through their effect on calcium regulation and inhibition of osteoblast function.

Special consideration should be given to patients with or at increased risk of osteoporosis (e.g., postmenopausal women) before initiating corticosteroid therapy.

5.12 Behavioral and Mood Disturbances

Corticosteroid use may be associated with new or aggravated adverse psychiatric reactions ranging from euphoria, insomnia, mood swings, and personality changes to severe depression and frank psychotic manifestations.

Special consideration should be given to patients with previous or current emotional instability or psychiatric illness before initiating corticosteroid therapy. Advise patients and/or caregivers to immediately report any new or worsening behavior or mood disturbances to their health care provider.

6 ADVERSE REACTIONS

The following serious adverse reactions are described elsewhere in the labeling.

- Serious Neurologic Adverse Reactions with Epidural and Intrathecal Administration [*see Warnings and Precautions (5.2)*]

- Hypersensitivity Reactions [*see Warnings and Precautions (5.3)*]
- Joint Infection and Damage [*see Warnings and Precautions (5.4)*]
- Increased Risk of Infections [*see Warnings and Precautions (5.5)*]
- Alterations in Endocrine Function [*see Warnings and Precautions (5.6)*]
- Cardiovascular Effects [*see Warnings and Precautions (5.7)*]
- Renal Effects [*see Warnings and Precautions (5.8)*]
- Increased Intraocular Pressure [*see Warnings and Precautions (5.9)*]
- Gastrointestinal Perforation [*see Warnings and Precautions (5.10)*]
- Alterations in Bone Density [*see Warnings and Precautions (5.11)*]
- Behavioral and Mood Disturbances [*see Warnings and Precautions (5.12)*]

6.1 Clinical Trials

Because clinical studies are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trials of another drug and may not reflect the rates observed in practice.

The data below reflect exposure to a single 32 mg intra-articular injection of ZILRETTA in clinical studies in patients with moderate to severe pain due to osteoarthritis of the knee. Clinical studies included randomized, double-blind, parallel-group, placebo and/or active-controlled, and pharmacokinetic/pharmacodynamic studies with follow-up ranging from 6-24 weeks. A total of 424 patients received ZILRETTA and 262 received placebo. Treatment emergent adverse reactions reported by greater than or equal to 1% of patients in the ZILRETTA arms are summarized below (**Table 1 and 2**).

Overall, the incidence and nature of adverse reactions was similar to that observed with placebo.

Table 1: Most Commonly Reported Treatment-Emergent Adverse Reactions with ZILRETTA (Incidence $\geq 1\%$) in Patients with Osteoarthritis of the Knee

Preferred Term (MedDRA)	ZILRETTA (N=424)	Placebo (N=262)
Sinusitis	2%	1%
Cough	2%	1%
Contusions	2%	1%

Table 2: Most Commonly Reported Treatment-Emergent Injected Knee Adverse Reactions with ZILRETTA (Incidence $\geq 1\%$) in Patients with Osteoarthritis of the Knee

Preferred Term (MedDRA)	ZILRETTA (N=424)	Placebo (N=262)
Joint Swelling	3%	2%
Contusions	2%	1%

The safety of repeat administration of ZILRETTA was evaluated in a multicenter, open-label, single-arm study in patients with osteoarthritis pain of the knee. A total of 179 patients received a repeat injection on or after Week 12 (median 16.6 weeks) and were followed for 52 weeks from the initial injection. As assessed by adverse event rates for the periods of baseline to second dose and second dose to the comparable period after the second dose, there were higher rates of reported mild to moderate arthralgia after the second dose (16%) than after the first dose (6%). The data from this study are insufficient to fully characterize the safety of repeat administration of ZILRETTA. *[See also Nonclinical Toxicology (13.2)].*

6.2 Post-marketing Experience

The following adverse reactions, presented alphabetically by body system, have been identified during post-approval use of ZILRETTA. Because these reactions are reported voluntarily from a population of uncertain size, it is not always possible to reliably estimate their frequency or establish a causal relationship to drug exposure.

Endocrine: Increased blood glucose (in diabetic patients).

General and administration site conditions: Pain including injection site pain or discomfort and leg pain.

Immune system: Hypersensitivity reactions including pruritus, rash, angioedema, and anaphylaxis *[see Contraindications (4), Warnings and Precautions (5.3)].*

Infections and Infestations: Septic arthritis *[see Warning and Precautions (5.4)].*

Musculoskeletal: Arthralgia, joint swelling or effusion, muscle spasms.

Nervous system: Headache.

Reproductive system: Postmenopausal vaginal bleeding (similar to a menstrual period).

Skin and Subcutaneous Tissue: Pruritus.

6.3 Corticosteroid Adverse Reactions

The following adverse reactions, presented alphabetically by body system, are from voluntary reports or clinical studies of corticosteroids. Because some of these reactions are reported voluntarily from a population of uncertain size, it is not always possible to reliably estimate their frequency or establish a causal relationship to drug exposure.

Anaphylactic reactions: Anaphylaxis including death, angioedema *[see Warnings and Precautions (5.3)].*

Cardiovascular: Bradycardia, cardiac arrest, cardiac arrhythmias, cardiac enlargement, circulatory collapse, congestive heart failure, hypertension *[see Warnings and Precautions (5.7)].*, fat embolism,

hypertrophic cardiomyopathy in premature infants, myocardial rupture following recent myocardial infarction, pulmonary edema, syncope, tachycardia, thromboembolism, thrombophlebitis, vasculitis.

Dermatologic: Acne, allergic dermatitis, cutaneous and subcutaneous atrophy, dry scaly skin, ecchymoses and petechiae, edema, erythema, hyperpigmentation, hypopigmentation, impaired wound healing, increased sweating, lupus erythematosus-like lesions, purpura, rash, sterile abscess, striae, suppressed reactions to skin tests, thin fragile skin, thinning scalp hair, urticaria.

Endocrine: Decreased carbohydrate and glucose tolerance, development of Cushingoid state, glycosuria, hirsutism, hypertrichosis, increased requirements for insulin or oral hypoglycemic agents in diabetes, manifestations of latent diabetes mellitus, menstrual irregularities, secondary adrenocortical and pituitary unresponsiveness (particularly in times of stress, as in trauma, surgery, or illness), suppression of growth in pediatric patients.

Fluid and electrolyte disturbances: Congestive heart failure in susceptible patients [*see Warnings and Precautions (5.7)*], fluid retention, sodium retention.

Gastrointestinal: Abdominal distention, bowel/bladder dysfunction (after intrathecal administration) [*see Warnings and Precautions (5.2)*], elevation in serum liver enzyme levels (usually reversible upon discontinuation), hepatomegaly, increased appetite, nausea, pancreatitis, peptic ulcer with possible perforation and hemorrhage, perforation of the small and large intestine (particularly in patients with inflammatory bowel disease) [*see Warnings and Precautions (5.10)*], ulcerative esophagitis.

Metabolic: Negative nitrogen balance due to protein catabolism.

Musculoskeletal: Aseptic necrosis of femoral and humeral heads, calcinosis (following intra-articular or intralesional use), Charcot-like arthropathy, loss of muscle mass, muscle weakness, osteoporosis, pathologic fracture of long bones, post injection flare (following intra-articular use), steroid myopathy, tendon rupture, vertebral compression fractures.

Neurologic/Psychiatric: Convulsions, depression, emotional instability, euphoria, headache, increased intracranial pressure with papilledema (pseudotumor cerebri) usually following discontinuation of treatment, insomnia, mood swings, neuritis, neuropathy, paresthesia, personality changes, psychiatric disorders [*see Warnings and Precautions (5.12)*], vertigo. Arachnoiditis, meningitis, paraparesis/paraplegia, and sensory disturbances have occurred after intrathecal administration. Spinal cord infarction, paraplegia, quadriplegia, cortical blindness, and stroke (including brainstem) have been reported after epidural administration of corticosteroids [*see Warnings and Precautions (5.2)*].

Ophthalmic: Exophthalmos, glaucoma, increased intraocular pressure [*see Warnings and Precautions (5.9)*], posterior subcapsular cataracts, rare instances of blindness associated with periocular injections.

Other: Abnormal fat deposits, decreased resistance to infection, hiccups, increased or decreased motility and number of spermatozoa, malaise, moon face, weight gain.

7 DRUG INTERACTIONS

No drug-drug interaction studies have been conducted with ZILRETTA. **Table 3** contains drug interactions associated with systemic corticosteroids.

Table 3: Drug Interactions Associated with Systemic Corticosteroids

Aminoglutethimide	Aminoglutethimide may lead to a loss of corticosteroid-induced adrenal suppression.
Amphotericin B injection and potassium-depleting agents	When corticosteroids are administered concomitantly with potassium-depleting agents (i.e., amphotericin B, diuretics), observe patients closely for development of hypokalemia. There have been cases reported in which concomitant use of amphotericin B and hydrocortisone was followed by cardiac enlargement and congestive heart failure.
Antibiotics	Macrolide antibiotics have been reported to cause a significant decrease in corticosteroid clearance.
Anticholinesterases	Concomitant use of anticholinesterase agents and corticosteroids may produce severe weakness in patients with myasthenia gravis. If possible, withdraw anticholinesterase agents at least 24 hours before initiating corticosteroid therapy.
Anticoagulants, oral	Coadministration of corticosteroids and warfarin usually results in inhibition of response to warfarin, although there have been some conflicting reports. Therefore, monitor coagulation indices frequently to maintain the desired anticoagulant effect.
Antidiabetics	Because corticosteroids may increase blood glucose concentrations, dosage adjustments of antidiabetic agents may be required.
Antitubercular drugs	Serum concentrations of isoniazid may be decreased.
CYP 3A4 inducers (e.g., barbiturates, phenytoin, carbamazepine, and rifampin)	Drugs which induce hepatic microsomal drug metabolizing enzyme activity may enhance metabolism of corticosteroids and require that the dosage of corticosteroid be increased.
CYP 3A4 inhibitors (e.g., ketoconazole)	Ketoconazole, a strong CYP3A4 inhibitor, has been reported to decrease the metabolism of certain corticosteroids by up to 60% leading to an increased risk of corticosteroid side effects.
Cholestyramine	Cholestyramine may increase the clearance of corticosteroids.
Cyclosporine	Increased activity of both cyclosporine and corticosteroids may occur when the two are used concurrently. Convulsions have been reported with this concurrent use.
Digitalis glycosides	Patients on digitalis glycosides may be at increased risk of arrhythmias due to hypokalemia.
Estrogens, including oral contraceptives	Estrogens may decrease the hepatic metabolism of certain corticosteroids, thereby increasing their effect.
Nonsteroidal anti-inflammatory drugs (NSAIDs)	Concomitant use of aspirin (or other nonsteroidal anti-inflammatory drugs) and corticosteroids increases the risk of gastrointestinal side effects. Aspirin should be used cautiously in conjunction with corticosteroids in hypoprothrombinemia. The clearance of salicylates may be increased with concurrent use of corticosteroids.
Skin tests	Corticosteroids may suppress reactions to allergy related skin tests.

Vaccines	Patients on prolonged corticosteroid therapy may exhibit a diminished response to toxoids and live or inactivated vaccines due to inhibition of antibody response. Corticosteroids may also potentiate the replication of some organisms contained in live attenuated vaccines. If possible, defer routine administration of vaccines or toxoids until corticosteroid therapy is discontinued.
----------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

8 USE IN SPECIFIC POPULATIONS

8.1 Pregnancy

Risk Summary

There are no data regarding the use of ZILRETTA in pregnant women to inform a drug associated risk of adverse developmental outcomes. Published studies on the association between corticosteroids and fetal outcomes have reported inconsistent findings and have important methodological limitations. The majority of published literature with corticosteroid exposure during pregnancy includes the oral, topical and inhaled dosage formulations; therefore, the applicability of these findings to a single intra-articular injection of triamcinolone acetonide is limited. In animal reproductive studies from the published literature, pregnant mice, rats, rabbits, or primates administered triamcinolone acetonide during the period of organogenesis at doses that produced exposures less than the maximum recommended human dose (MRHD) caused resorptions, decreased fetal body weight, craniofacial and/or other abnormalities such as omphalocele (*see Data*).

The estimated background risk of major birth defects and miscarriage for the indicated population is unknown. All pregnancies have a background risk of birth defect, loss, or other adverse outcomes. In the U.S. general population, the estimated risk of major birth defects and miscarriage in clinically recognized pregnancies is 2% to 4% and 15% to 20%, respectively.

Data

Animal Data

The exposure margins listed below are based on body surface area comparisons (mg/m²) to the highest daily triamcinolone acetonide exposure at the MRHD of 32 mg triamcinolone acetonide via ZILRETTA.

Pregnant mice dosed with triamcinolone acetonide via intramuscular or subcutaneous injection at doses equivalent to 0.8 times the MRHD or higher during organogenesis caused cleft palate and a higher rate of resorption. In pregnant rats dosed with triamcinolone acetonide via intramuscular or subcutaneous injection at doses equivalent to 0.3 times the MRHD or higher during organogenesis caused developmental abnormality (cleft palate, omphalocele, late resorption, and growth retardation) and fetal mortality. No notable maternal toxicity was observed in rodents.

Pregnant rabbits dosed with triamcinolone acetonide via intramuscular injection for 4 days during organogenesis at doses equivalent to 0.15 times the MRHD or higher caused resorption and cleft palate. No notable maternal toxicity was observed.

Pregnant primates dosed with triamcinolone acetonide via intramuscular injection for 4 days during organogenesis at doses equivalent to 3 times the MRHD or higher caused severe craniofacial CNS and skeletal/visceral malformation and higher prenatal death. No notable maternal toxicity was observed.

No peri- and post-natal development studies of triamcinolone acetonide in animals have been conducted.

8.2 Lactation

Risk Summary

There are no available data on the presence of triamcinolone acetonide in either human or animal milk, the effects on the breastfed infant, or the effects on milk production. However, corticosteroids have been detected in human milk and may suppress milk production. It is not known whether intra-articular administration of ZILRETTA could result in sufficient systemic absorption to produce detectable quantities in human milk. The developmental and health benefits of breastfeeding should be considered along with the mother's clinical need for ZILRETTA and any potential adverse effects on the breastfed infant from ZILRETTA or from the underlying maternal condition.

8.3 Females and Males of Reproductive Potential

Corticosteroids may result in menstrual pattern irregularities such as deviations in timing and duration of menses and an increased or decreased loss of blood.

8.4 Pediatric Use

The safety and effectiveness of ZILRETTA in pediatric patients have not been established.

The adverse effects of corticosteroids in pediatric patients are similar to those in adults. Carefully observe pediatric patients, including weight, height, linear growth, blood pressure, intraocular pressure, and clinical evaluation for the presence of infection, psychosocial disturbances, thromboembolism, peptic ulcers, cataracts, and osteoporosis. Weigh potential growth effects of treatment against clinical benefits obtained and the availability of treatment alternatives.

8.5 Geriatric Use

Of the total number of patients administered 32 mg ZILRETTA in clinical studies (N=424), 143 patients were 65 years of age or older. No overall differences in safety or effectiveness were observed between elderly and younger subjects, and other reported clinical experience with triamcinolone acetonide has not identified differences in responses between the elderly and younger patients, but greater sensitivity of some older individuals cannot be ruled out.

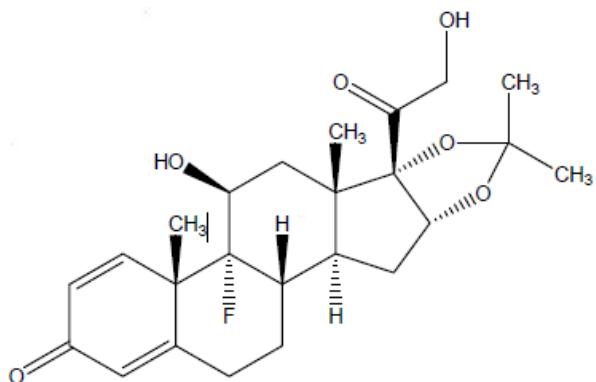

11 DESCRIPTION

ZILRETTA (triamcinolone acetonide extended-release injectable suspension) is a microsphere formulation of triamcinolone acetonide, a corticosteroid, to be administered by intra-articular injection.

ZILRETTA is formulated in 75:25 poly(lactic-co-glycolic acid) (PLGA) microspheres with a nominal drug load of 25% (w/w) and is provided as a sterile white to off-white powder. ZILRETTA is prepared with a supplied diluent containing an isotonic, sterile, aqueous solution of sodium chloride (NaCl; 0.9% w/w), sodium carboxymethylcellulose (CMC; 0.5% w/w), polysorbate-80 (0.1% w/w) and with sodium hydroxide (NaOH) and hydrochloric acid (HCl) as pH adjusters, as required to form a 5 mL sterile suspension intended for intra-articular injection.

Active Ingredient

The chemical name for triamcinolone acetonide is 9-fluoro-11 β ,16 α ,17,21-tetrahydroxypregna-1,4-diene-3,20-dione cyclic 16,17-acetal with acetone. Its structural formula is:

MW 434.50 with a molecular formula of C₂₄H₃₁FO₆

Triamcinolone acetonide occurs as a white to almost white, crystalline powder having not more than a slight odor and is practically insoluble in water and very soluble in alcohol. Each vial of ZILRETTA powder contains 40 mg of triamcinolone acetonide in 160 mg of microspheres, resulting in 32 mg of deliverable triamcinolone acetonide when prepared according to the Instructions for Use.

12 CLINICAL PHARMACOLOGY

12.1 Mechanism of Action

Triamcinolone acetonide is a corticosteroid with anti-inflammatory and immunomodulating properties. It binds to and activates the glucocorticoid receptor, leading to activation of anti-inflammatory transcription factors such as lipocortins and inhibition of inflammatory transduction pathways by blocking the release of arachidonic acid and preventing the synthesis of prostaglandins and leukotrienes.

12.2 Pharmacodynamics

Studies indicate that following a single intramuscular dose of 60 to 100 mg of immediate-release triamcinolone acetonide injectable suspension, adrenal suppression occurs within 24 to 48 hours and then gradually returns to normal, usually in 30 to 40 days. To assess potential effects of the systemic levels of triamcinolone acetonide associated with a single intra-articular (IA) administration of ZILRETTA on hypothalamic pituitary adrenal (HPA) axis function, serum and urine cortisol levels were monitored over 6 weeks post injection. Adrenal suppression with ZILRETTA occurred within 12-24 hours and then gradually returned to normal, within 30-42 days.

Corticosteroids may increase blood glucose concentrations.

In a study where 18 patients with osteoarthritis knee pain and controlled type 2 diabetes mellitus received a single IA injection of ZILRETTA into the knee, the change from baseline in average blood glucose over the 72 hours after injection as measured by a continuous glucose monitoring device was 8.2 mg/dL (95% confidence interval 0.1, 29.2).

12.3 Pharmacokinetics

ZILRETTA is an extended-release dosage form consisting of microspheres of poly(lactic-co-glycolic acid) (PLGA) containing triamcinolone acetonide. Plasma pharmacokinetic parameters for triamcinolone acetonide following IA administration of ZILRETTA or 40 mg immediate-release triamcinolone acetonide into the knee are provided in **Table 4**.

Table 4: Summary of Mean (SD) Plasma Pharmacokinetic Parameters for Triamcinolone Acetonide Following IA Administration of ZILRETTA or 40 mg Immediate-Release Triamcinolone Acetonide

Triamcinolone Acetonide PK Parameters ¹	ZILRETTA (N=60)	Triamcinolone Acetonide (N=18)
C _{max} (pg/mL)	1,143.7 (611.06)	21,062.2 (18,466.79)
AUC _{0-24 hour} (pg•h/mL)	21,219.2 (11,325.62)	297,545.3 (222,402.77)
AUC _{0-inf} (pg•h/mL)	842,149.2 (1,062,004.97)*	1,567,565.0 (1,246,330.95) [†]
t _{max} (h)	7 (1, 1,008)	6 (2, 24)
t _{1/2} (h)	633.9 (893.0)*	146.9 (213.29) [†]

* 33 patients contributed to the analyses of these parameters

† 14 patients contributed to the analyses of these parameters

1 Median (min, max) values for t_{max}

13 NONCLINICAL TOXICOLOGY

13.1 Carcinogenesis, Mutagenesis, Impairment of Fertility

Carcinogenesis

Long-term animal studies to evaluate the carcinogenic potential of ZILRETTA have not been conducted.

Mutagenesis

Adequate mutagenicity studies have not been conducted with ZILRETTA.

Impairment of Fertility

Studies in animals to evaluate the impairment of fertility of ZILRETTA have not been conducted.

13.2 Animal Toxicology and/or Pharmacology

Single and repeat administrations (one injection every three months for a total of three injections) of ZILRETTA in non-arthritic knee joints of healthy dogs have been studied at ~1.9 times the maximum recommended human dose (MRHD) of 32 mg (based on estimated drug concentrations within the knee joints). ZILRETTA microspheres were degraded by approximately 4-and 6-months post dosing in single and repeat dose studies, respectively.

Single administration resulted in a slightly increased incidence, severity (minimal to slight), and/or duration of microscopic changes (infiltration of macrophages, lymphocytes, plasma cells and fibrosis) and decreased Safranin O staining (decreased proteoglycan content in the cartilage of the knees) compared to administration of an equivalent dose of immediate-release triamcinolone acetonide. These responses were mostly reversed after 6 to 9 months post injection.

Repeat administration resulted in an increase in the incidence, severity (minimal to slight) and duration of microscopic changes (infiltration of macrophages, lymphocytes, plasma cells, neutrophils; fibrosis; neovascularization; granulation tissue; and debris) and decreased Safranin O staining (decreased proteoglycan content in the cartilage of the knees) compared to the equivalent dose of immediate-release triamcinolone acetonide. These local responses were still reversing at 6 months post the last injection. No effect on the animals according to observations related to gait/walking, pain/discomfort in the injected knee, local swelling, local redness or local tenderness were noted.

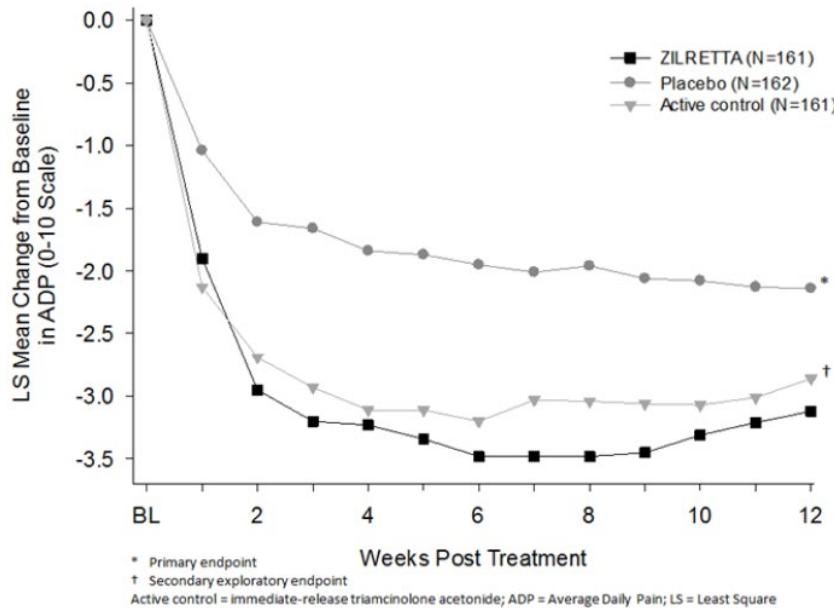

The clinical relevance of these findings in the arthritic knee is unknown.

14 CLINICAL STUDIES

The efficacy of ZILRETTA was demonstrated in a multi-center, international, randomized, double-blind, parallel-arm, placebo- and active-controlled study in patients with osteoarthritis pain of the knee. A total of 484 patients (ZILRETTA 32 mg, N=161; placebo [saline], N=162; active control [a crystalline suspension, immediate-release formulation of triamcinolone acetonide 40 mg], N=161) were treated and followed for up to 24 weeks. Patients had a mean age of 62 (range 40 to 85 years); baseline demographics and disease characteristics were balanced across treatment arms. Twenty-five percent (25%) of patients had received at least one prior corticosteroid intra-articular injection more than 3 months prior to treatment. A total of 470 patients (97%) completed follow-up to Week 12, the time point for primary efficacy determination, and 443 (91.5%) completed to Week 24.

The primary efficacy endpoint comparing ZILRETTA to placebo was change from baseline at Week 12 in the weekly mean of the Average Daily Pain intensity scores (ADP) as assessed by a 0-10 Numeric Rating Scale (NRS). ZILRETTA demonstrated a statistically significant reduction in pain intensity at the primary endpoint vs placebo. ZILRETTA also demonstrated a reduction in pain intensity scores each week from Weeks 1 through 12 (**Figure 1**).

Figure 1: Weekly Change from Baseline to Week 12 in Average Daily Pain

16 HOW SUPPLIED/STORAGE AND HANDLING

Description	NDC	Presentation/How Supplied
ZILRETTA	NDC 65250-003-01	ZILRETTA (triamcinolone acetonide extended-release injectable suspension) single-dose kit.
Kit Contents		
ZILRETTA microsphere powder	NDC 65250-001-01	Single-dose vial to deliver 32 mg of triamcinolone acetonide supplied as a sterile, white to off-white powder in a cerium glass (clear) vial with a rubber stopper and an aluminum seal with a gray plastic cap.
Diluent	NDC 65250-002-01	5 mL single-dose vial supplied as a sterile, colorless to pale yellow, clear liquid solution of 0.9% w/w sodium chloride (normal saline) containing 0.5% w/w sodium carboxymethylcellulose, and 0.1% w/w polysorbate-80 in a glass vial with a rubber stopper, aluminum seal and white plastic cap.
Sterile vial adapter		

STORAGE

To maintain expiry period, refrigerate the ZILRETTA single-dose kit 2-8°C (36-46°F) before use.

If refrigeration is unavailable, store the ZILRETTA single-dose kit in the sealed, unopened kit at temperatures not exceeding 25°C (77°F) for up to three weeks and then discard. Do not expose the ZILRETTA single-dose kit to temperatures above 25°C (77°F).

Do not freeze. Store vials in carton.

17 PATIENT COUNSELING INFORMATION

Increased Risk of Infections

Inform patients that they may be more likely to develop infections when taking corticosteroids. Instruct patients to contact their health care provider if they develop fever or other signs or symptoms of infection.

Advise patients who have not been vaccinated to avoid exposure to chicken pox or measles. Instruct patients to contact their health care provider immediately if they are exposed [*see Warnings and Precautions (5.5)*].

Risk of Drug Interactions

There are a number of medicines that can interact with corticosteroids such as triamcinolone acetonide. Advise patients to alert their health care provider(s) to assess the need to adjust their medication(s) [*see Drug Interactions (7)*].

Risk of Adverse Psychiatric Reactions

Inform patients that corticosteroid use may be associated with adverse psychiatric reactions. Advise patients and/or caregivers to immediately report any new or worsening behavioral or mood disturbances to their health care provider [*see Warnings and Precautions (5.12)*].
